It is used to compute brightness in the zenith direction ( i. e. , looking straight up ) only. To correct this, the effects of off-angle views and the corresponding corrections to the zenith brightness were made. Berry ( 12 ) points out that, to a first approximation, we can assume that light originating from a city is scattered through an optically thin uniform layer of the atmosphere. The brightness of the layer is then proportional to a line-of-sight ( LOS ) thickness through the scattering layer. The LOS through a layer is proportional to the secant of the zenith angle; therefore, city lights, when viewed from far away, would appear to increase in brightness as the secant of the zenith angle. To emulate this, a function was introduced to correct the zenith brightness for variations in zenith angle:  $f(z) = A \sec(z)$ , ( 2 ) where A is a constant of proportionality determined from empirical data and z is the zenith angle in degrees. Using data from Berry ( 12 ), Walker ( 3 ), and Garstang ( 7...
